I. INTRODUCTION
The practice of medicinal chemistry is devoted to the discovery and development of new agents for treating disease. The process of establishing a new drug is exceeding complex and involves talent of people from variety of disciplines [1].

The design of drug molecules arguably offers some of the greatest hopes for success in present and future era. Heterocyclic compounds are widely distributed in nature and are essential for life. There are vast numbers of pharmacologically active heterocyclic compounds many of which are in regular clinical use [2].

Thiophene (Fig.1) belongs to a class of heterocyclic compounds containing a five membered ring made up of one sulphur as heteroatom with the formula $C_4H_4S$. Thiophene and its derivatives exist in petroleum or coal. Thiophene is taken from the word theion, the Greek word for sulfur, and another Greek word phaino which means shining. Thiophene structure can be found in certain natural products and is also incorporated in several pharmacologically active compounds.

![Figure 1. Structure of Thiophene](image)

The simple thiophenes are stable liquids which closely resemble the corresponding benzene compounds in boiling point and even in smell [3]. Thiophene was discovered as a contaminant in benzene [4]. It was observed that isatin (1H-indole-2, 3- Dione) forms a blue dye if it is mixed with sulfuric acid and crude benzene. Victor Meyer was able to isolate the substance responsible for this reaction. The compound was found to be a heterocyclic compound- Thiophene.
II. VARIOUS SYNTHETIC ROUTES FOR THIOPHENE NUCLEUS FORMATION

A method of preparing thiophene involves reaction of an organic compound containing a chain of at least four carbon atoms linked by single or double bonds with a source of sulphur. The nature and type of the synthesized substituted thiophene compounds depends on the starting material. Thus a starting material containing solely four carbon atoms in a straight chain produces unsubstituted thiophene while those containing more than four carbon atoms lead to synthesis of substituted thiophene.

Various synthetic approaches to the construction of thiophene and substituted thiophene have been efficiently developed. Thiophene ring can be constructed from non-heterocyclic precursors by two reaction pathways [5]:

a. Construction of thiophene ring from appropriately substituted open chain precursors: This method involves the introduction of sulphur into a starting material containing the complete carbon skeleton.

b. The functionalization at the positions α and β to the sulphur atom of the preconstructed thiophene nucleus: This method employs either the reaction of a mercaptoacetate with a 1, 3-dicarbonyl compound or the reaction of a thiodiacetate with a 1, 2-dicarbonyl compound.

III. GENERAL SYNTHETIC ROUTES FOR THIOPHENE NUCLEUS FORMATION

The general synthetic procedure includes the following:

- From thiazoles: When thiazoles are heated strongly with an alkyne, generates 2, 5-unsubstituted thiophenes. Though the conditions are vigorous, excellent yield can be obtained. (Fig. 2)

\[
\begin{align*}
\text{Ph} & \quad \rightarrow \quad \text{SiMe}_3 \text{SiMe}_3 \\
\text{F}_{\text{c}} & \quad \text{Me}_3 \text{SC} = \text{CSiMe}_3 \quad \text{DBU} \\
\end{align*}
\]

- By carbon disulfide: 2-alkylthiophenes [6] can be synthesized by the addition of a carbanion to carbon disulfide with a subsequent S-alkylation. (Fig. 3)

\[
\begin{align*}
\text{CH}_3\text{CO} & \quad \rightarrow \quad \text{S} \\
\text{c} & \quad \text{CS}_2, \text{K}_2\text{CO}_3 \quad \text{DMF} \\
\end{align*}
\]

- From thio-nitroacetamides: The S-alkylation of thio-nitroacetamides with 2-bromoketones produces 2-amino-3-nitrothiophenes [7]. (Fig. 4)
IV. MAJOR SYNTHETIC ROUTES FOR THIOPHENE NUCLEUS FORMATION

The major synthetic procedures for the synthesis of thiophene moiety includes following:

- Paal-Knorr Thiophene Synthesis: This reaction is also known as Paal Thiophene Synthesis. In this, 1, 4-Dicarbonyl compounds are reacted with a source of sulfur to give thiophene. (Fig. 6)

Source of sulfur used are traditionally phosphorus sulfides, latterly Lawesson’s reagent (LR) or bis(trimethylsilyl) sulfide [9]. (Fig. 7)
• Fieselmann Thiophene Synthesis: Condensation reaction of thioglycolic acid with α, β- acetylenic esters, which upon treatment with base result in the formation of 3- hydroxyl- 2-thiophene carboxylic acid [10]. (Fig. 8)

![Figure 8](image)

• Gewald Aminothiophene Synthesis: This method was reported by Gewald in 1966 [11]. Gewald synthesis is the usual route to 2-aminothiophenes. It consists of the base-catalyzed condensation of a ketone having a CH$_2$ group with a β-ketonitrile to form an olefin, followed by cyclisation with elemental sulfur. (Fig. 9)

![Figure 9](image)

• The Hinsberg Synthesis: Two consecutive aldol condensations between a 1, 2-dicarbonyl compound and diethyl thiodiacetates gives thiophene. The immediate product is an ester-acid produced [12] by a Stobbe-type mechanism but the reactions are often worked up via hydrolysis to afford an isolated diacid. (Fig. 10)

V. MEDICINAL IMPORTANCE OF THIOPHENE

In medicinal chemistry, thiophene derivatives have been very well known for their therapeutic applications. Although thiophene have been known from long ago to be biologically active, their varied biological features are still of great scientific interest.
Thiophene can be fused with various heterocyclic systems giving rise to various new heterocyclic system with enhanced biological activity. Thienopyrimidines occupy a special position among these compounds.

VI. CONCLUSION

The analytical and other informational data, available in literature so far, have rendered thiophene significantly important class of heterocyclic compounds and their applications in ever challenging chemotherapy of various ailments/ infections since last two decades immensely hiked interests of medicinal chemist and biochemist. It has been seen that the thiophene analogues incorporated with different nuclei have shown variety of pharmacological profiles. Fused hetero-
aromatic systems are often of greater interest than monocyclic compounds as far as the biological activity is concerned. Thiophene can be fused with various heterocyclic systems resulting in various new heterocyclic systems with enhanced biological activity.

This particular review article, established the fact that thiophene derivatives could be a rich source of potential entities in search of new generation of biologically active compounds and be worthwhile to explore the possibility in this area by fusing differently substituted moieties which may result in better pharmacological activities. Thus the quest to explore many more modifications on thiophene moiety needs to be continued.
